

Perturbation theory is a correctness feature, not a throughput one

1920×1080, max_iter=1000, seahorse valley. Plain scalar f64 is faster than perturbation at every zoom tested — series approximation skips only 2-36 iterations of 1000 for this reference point. Perturbation earns its place past f64's $\sim 1e15$ ceiling, where scalar iteration cannot resolve individual pixels at all; that regime is beyond what this sweep measures.
